

DNS Walkthrough

How my FlyRank subdomain will point to my site, PF-04

What a CNAME record is

A CNAME record basically works like a nickname. It lets you point a domain or subdomain to another official domain name. For example, with `www`: whether someone types `www` or not, they get taken to the same site.

What my record will hold

The nickname

ArthurDavino.flyrank.ai

Points to the official domain

arthurdavino.github.io

Once my subdomain is provisioned, this is the one record that connects `arthurdavino.flyrank.ai` to the site that is already live and already working today.

What actually happens when someone types my address

When the user types the subdomain and hits enter, the resolver receives that request and asks someone called the nameserver. The nameserver answers with the record, which is the CNAME. After that, the resolver figures out the site's real IP address and sends the response back to the browser to load the page.

What this means in plain terms

Once the subdomain is added in my host settings and this CNAME record is set, DNS is not hosting or storing any content of mine. It is only the address book that tells the internet where the real site, still living on GitHub Pages, actually is. Nothing about how the site is built or deployed changes when the domain changes, only how people find it.
