

Explain It Like You Built It

Week 6, Task 1, one real piece of my build

HTML structure: tags, children, and what paste actually does

Regarding HTML, elements usually come in pairs, an opening tag and a closing tag (`<div>` and `</div>`). Anything contained within these elements acts as a “child” of that element, essentially, something nested inside something else. A `<div>`, for instance, can contain multiple child elements, such as other `<div>`'s, links, and so on. In my own experience with HTML, I ran into a slightly tricky situation: I tried to paste a line of code into my HTML, but ended up with two identical, duplicated lines. That’s when I realized I hadn't replaced the existing line; I had simply added a new one. Pasting a line of code doesn't automatically replace anything; it just adds the new line wherever you placed it.
